Decision Record D-001

Field	Value
Decision	The primary mechanism for claim verification will be a manual review by an administrator, with private evidence (e.g., serial numbers, unique marks) reviewed exclusively by the administrator.
Rationale	While automated matching is a key feature and will provide suggested matches only, the final claim approval requires human judgment to verify proof of ownership and mitigate the risk of fraudulent claims. An automated system cannot fully assess the nuance of ownership proof. Additionally, ownership evidence must remain private to prevent malicious users from using publicly visible evidence to falsely claim items.
Alternative Considered	Fully automated matching and claim approval without human intervention. This was rejected because it poses significant security and fraud risks, as automated systems cannot reliably distinguish between legitimate and fraudulent claims based on evidence alone.
Consequence	This introduces a dependency on a human actor for a critical path in the workflow. The system design must support: (1) an efficient administrative interface for reviewing claims and evidence, (2) secure storage of private evidence with RBAC (Role-Based Access Control) limiting access to administrators only, (3) tracking of all claim-related actions to ensure an auditable and transparent process, and (4) a chain-of-custody record that documents every status change (LOST → FOUND → CLAIMED → VERIFIED → RESOLVED/REJECTED). This decision directly influences the design of the claim, admin, and chain-of-custody modules.
Related Design-Suitability Check	This decision satisfies the "Important business/validation/security rule" and "At least one state-sensitive workflow or entity" checks in Section 9 of the proposal.
